

# Lecture VIII - Police Districting

Applied Optimization with Julia

Dr. Tobias Vlćek

University of Hamburg - Fall 2024

# Introduction

# Police Service District Planning

# Challenges

**Question:** What makes the work of emergency services complex?

- Dynamic urban development
- Changing population patterns
- Resource constraints
- Need for rapid response
- Multiple stakeholder interests

# Emergency Services

Emergency services address the needs of **three interest groups**:

- Citizens
- Service personnel
- Administrators

**Question:** What could be the objectives of these groups?

# Stakeholder Objectives

## 1. Citizens

- Fast response times
- Reliable service coverage

## 2. Service Personnel

- Manageable workloads
- Safe working conditions

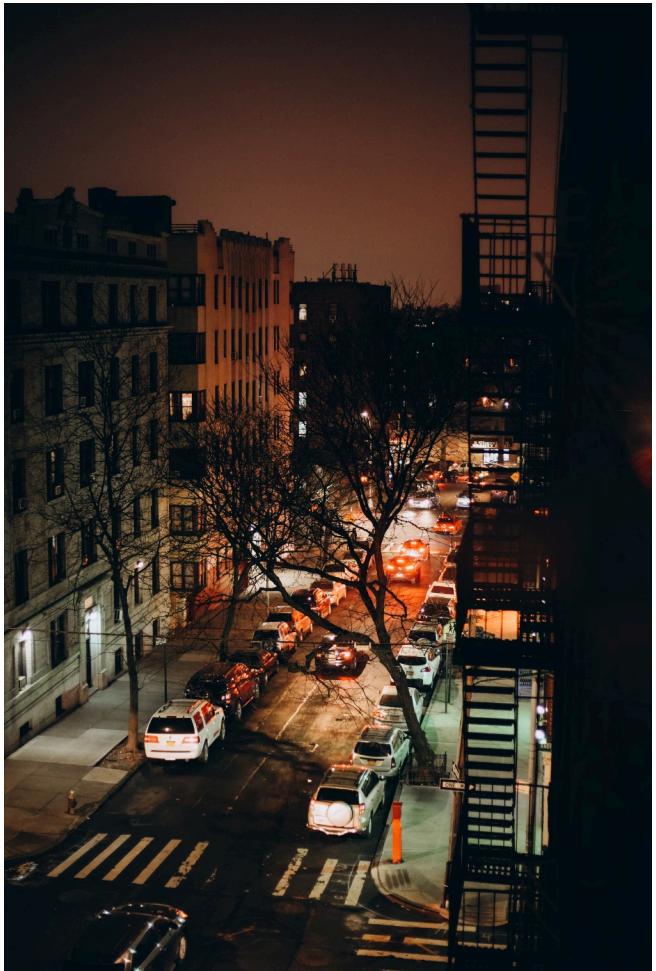

## 3. Administrators

- Cost efficiency
- Resource optimization

### Note

Aligning the objectives of the three interest groups is challenging.

# Emergency Service Districting

**Question:** Why might current district layouts be suboptimal?

- Many layouts **date back several decades**
- Often designed along highways and regions (**Bruce 2009**)
- Extensive data **not used** for data-driven improvement

How can we improve  
this situation?

# The Role of Data

**Question:** What data can help improve emergency services?

- Historical incident patterns
- Response time analysis
- Resource utilization metrics
- Population densities and traffic patterns

Note

Extensive data collected, but often **lack of tools or knowledge** to leverage it.

# Optimization

- Operations research (OR) models can help!
- Based on incident records and geographical information
- Improve the response of emergency services
- Help administrators in making strategic decisions
- Locate new departments or close departments (Liberatore, Camacho-Collados, and Vitoriano 2020)

# Case Studies

# Police Districting

For an efficient and effective distribution of resources, police jurisdictions are divided into precincts or command districts with separate departments. These are further divided into patrol beats (D'Amico et al. 2002).

# Service Priority Extremes

- **High Priority**
  - Life-threatening situations
  - Active crimes in progress
  - Multiple unit response needed
- **Low Priority**
  - Minor incidents
  - Administrative tasks

# Case Studies

- Different urban contexts
- Study of jurisdictions in
  - Germany: Large metropolitan area
  - Belgium: Large rural area
- Focus on response time optimization

Note

Part of the force patrols the streets, another part is **stationed at the departments**.

# Dispatching

- Dispatchers assign all CFS to vehicles from the **corresponding districts and patrol areas**
- Officers are **familiar with the area** and are thus better prepared to respond appropriately (**Bodily 1978**)
- To cope with high demands, dispatchers can **assign vehicles from nearby districts or beats**

# Potential Problem

**Question:** What could be the potential problem?

- This can lead to a **domino effect**
- Transferring vehicles from other districts or beats **reduces coverage in those locations** (Mayer 2009)
- This makes them vulnerable to missing resources when **they need assistance themselves**

# Overloaded Systems

- This can lead to **overloaded systems!**
- Long dispatching delays due to **staff shortages**
- Preventive patrol hardly possible (**Miller and Knoppers 1972**)
- Dispatchers **constantly** draw on patrol resources
- Reduces the **response time** of emergency services

## Warning

This is a **common problem** in many emergency services.

# Response Time

- Central criterion to measure the **effectiveness of emergency services** is the response time
- Time between a **call for aid** and the arrival at the **incident location**
- Low response time increases the likelihood of helping and improves confidence (**Bodily 1978**)

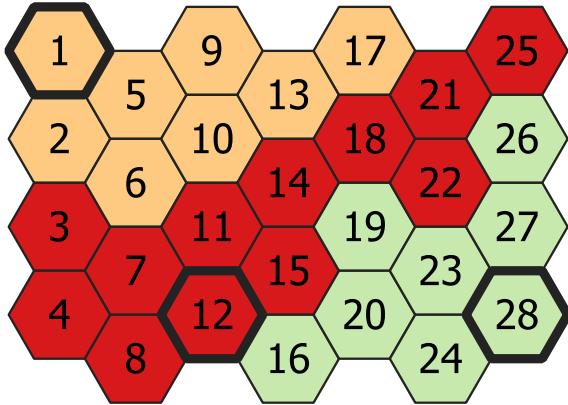

# Response Time Influencers

**Question:** What affects response time?

- Initial contact
- Information gathering
- Unit assignment
- Resource coordination
- Route to location
- Traffic conditions

# Territory Design Problem

# Territory Design Problem

Aggregation of small geographic areas, called basic areas (BAs), into geographic clusters, called districts, so that these are acceptable according to pre-defined planning criteria<sup>1</sup>.

1. Zoltners and Sinha (1983)

# Objective

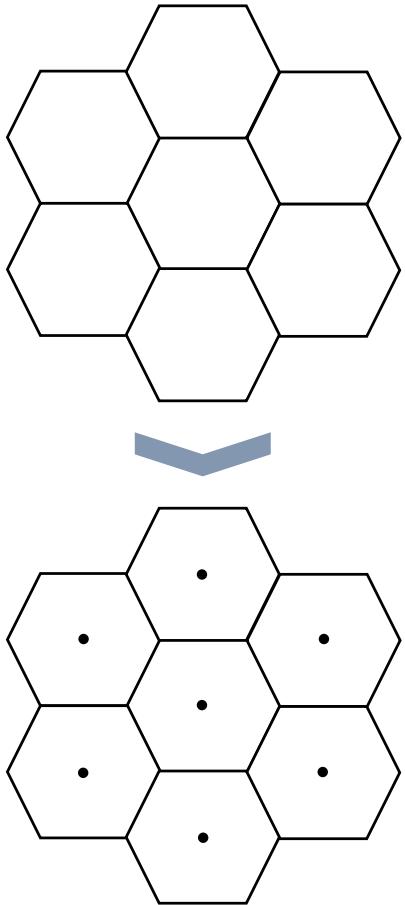

**Question:** What could be the objective?

- **Minimize the response time** to help citizens faster while increasing the confidence in the service

**Question:** What could be further objectives?

- Reallocate **only part** of the police department's
- Compact and contiguous territories to **improve patrol**
- Prevention of **isolated departments**

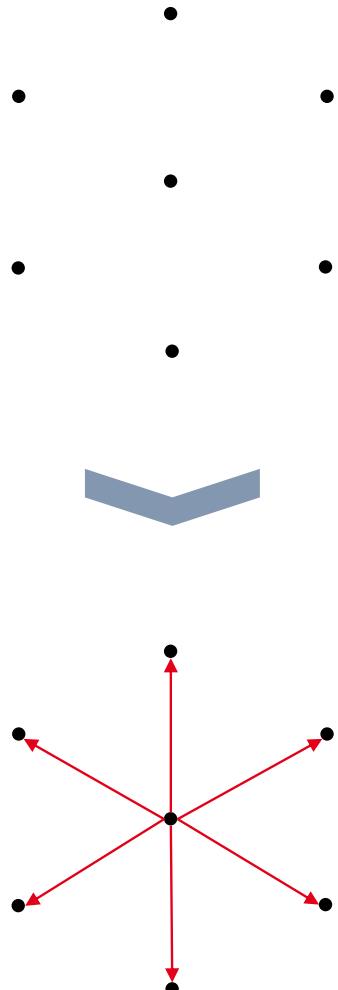

# Basic Structure

**Question:** How can we structure this?

- Model as a **digraph** with vertices and edges
- Each BA centroid becomes a **vertex**
- $\mathcal{J}$ : set of BAs, indexed by  $j$
- $\mathcal{I}$ : set of potential district centres ( $\mathcal{I} \subseteq \mathcal{J}$ )

# Why Hexagons?

## Question: Advantages of hexagons?

- Equal distances to all neighboring centroids
- Reduces sampling bias from edge effects  
(Wang and Kwan 2018)
- Special properties that help with the enforcement of compactness
- Better representation of urban geography

# Response Time Components

**Question: How can we model response time?**

- Call length is **independent** of territory
- Dispatch time is **difficult to model**
- Driving time can be **minimized directly**

**Conclusion**

We focus on **minimizing expected driving times** between departments and incident locations.

# Model Formulation

Let's build our model  
step by step!

# Key Model Components

**Question:** What could be our key model components?

- Basic areas (BAs) and potential department locations
- Driving times between basic areas
- Forecasted incident data
- Assignment decisions

**Question:** Which are sets, parameters, and variables?

# Sets and Indices

- $\mathcal{J}$  - Set of BAs, indexed by  $j$
- $\mathcal{I}$  - Set of potential district centres ( $\mathcal{I} \subseteq \mathcal{J}$ ), indexed by  $i$

 Note

The depot locations are a **subset** of the basic areas!

# Parameters

**Question:** What parameters do we need?

- $p$  - Number of district centres (departments)
- $t_{i,j}$  - Expected driving times between  $i$  and  $j$

Tip

Parameters should be carefully calibrated with real-world data!

# Decision Variable(s)?

 We have the following sets:

- BAs, indexed by  $j \in \mathcal{J}$
- Potential department locations, indexed by  $i \in \mathcal{I}$

 Our objective is to:

**Minimize the expected response time** of the emergency services by optimizing the assignment of BAs to departments.

**Question:** What decisions do we need to model?

# Decision variable/s

- $X_{i,j}$ : 1 if BA  $j$  assigned to department  $i$ , 0 otherwise

**Question:** What is the domain of our decision variable?

- $X_{i,j} \in \{0, 1\} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J}$

Let's build our  
objective function!

# Objective Function?

! Our objective is to:

Minimize the expected response time of the emergency services by optimizing the assignment of BAs to departments.

**Question:** How do we minimize response time?

- We want to minimize **total driving time**
- Consider frequency of incidents in each BA
- Don't include fixed costs (handled by constraints)

# Objective Function

**Question:** What could be our objective function?

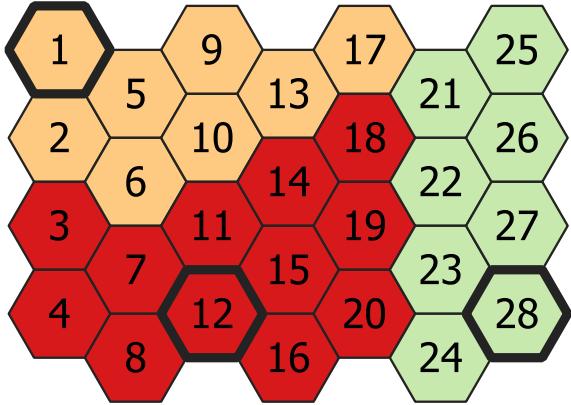

$$\text{minimize} \quad \sum_{i \in \mathcal{I}} \sum_{j \in \mathcal{J}} t_{i,j} \times X_{i,j}$$

## ! Expected Driving Time

- Total driving time **across all assignments**
- Weighted by **incident frequency**
- **Considers all possible BA-department pairs**

# Constraints

# Key Constraints

**Question:** Constraints needed?

1. BA must have **one** department
2. Limit **number of departments**
3. Only assign **active** departments
4. Ensure **contiguous** districts
5. Maintain district **compactness**

# Single Assignment Constraint?

**Question:** Why do we need this constraint?

- Each BA must be assigned to **exactly one** department
- Prevents **overlapping jurisdictions**
- Ensures **complete coverage**

We need the following variables:

- $X_{i,j}$  - 1 if BA  $j$  assigned to department  $i$ , 0 otherwise

# Single Assignment Constraint?

**Question:** What could the constraint look like?

$$\sum_{i \in \mathcal{I}} X_{i,j} = 1 \quad \forall j \in \mathcal{J}$$

## Note

Each BA must be assigned to exactly one department.

# Department Count Constraint?

! The goal of these constraints is to:

Ensure that exactly  $p$  departments are opened.

(i) We need the following sets and variables:

- $\mathcal{I}$  - Set of potential department locations, indexed by  $i$
- $\mathcal{J}$  - Set of BAs, indexed by  $j$
- $X_{i,j}$  - 1, if BA  $j$  assigned to department  $i$ , 0 otherwise
- $p$  - Number of departments

# Department Count Constraint

**Question:** What could the constraint look like?

$$\sum_{i \in \mathcal{I}} X_{i,i} = p$$

**Question:** What happens if we have more departments than potential locations?

- We can't open more departments than there are locations
- The model will be infeasible

# Active Department Constraint?

! The goal of these constraints is to:

Ensure that each BA is assigned to an active department, e.g. a department that is opened and that could dispatch vehicles.

i We need the following sets and variables:

- $X_{i,j}$  - 1, if BA  $j$  assigned to department  $i$ , 0 otherwise

**Question:** How do we ensure assignments only to active departments?

# Active Department Constraint

$$X_{i,j} \leq X_{i,i} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J}$$

## Note

This constraint creates a **logical connection between department locations and BA assignments** where BAs can only be assigned to **opened** departments.

# p-Median Problem

$$\text{minimize} \quad \sum_{i \in \mathcal{I}} \sum_{j \in \mathcal{J}} t_{i,j} \times X_{i,j}$$

$$\text{subject to:} \quad \sum_{i \in \mathcal{I}} X_{i,j} = 1 \quad \forall j \in \mathcal{J}$$

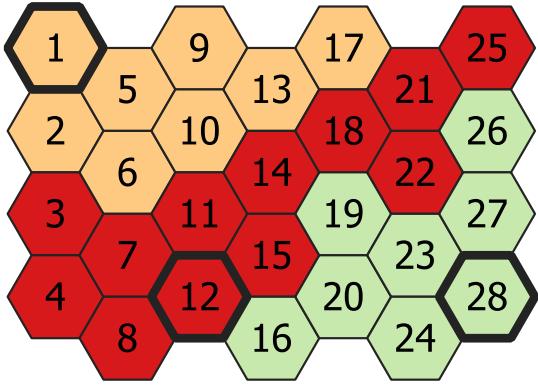

$$\sum_{i \in \mathcal{I}} X_{i,i} = p$$

$$X_{i,j} \leq X_{i,i} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J}$$

$$X_{i,j} \in \{0, 1\} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J}$$

# Contiguity and Compactness

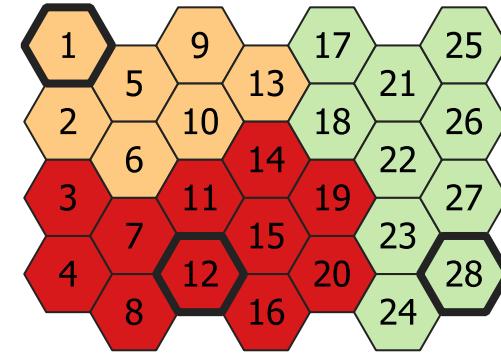

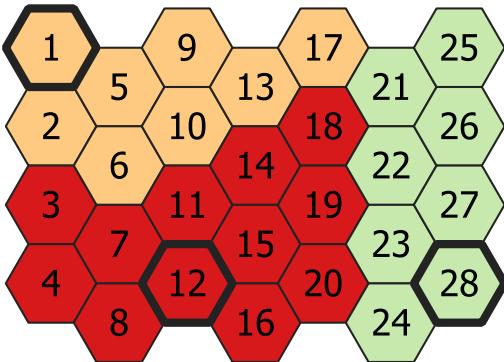

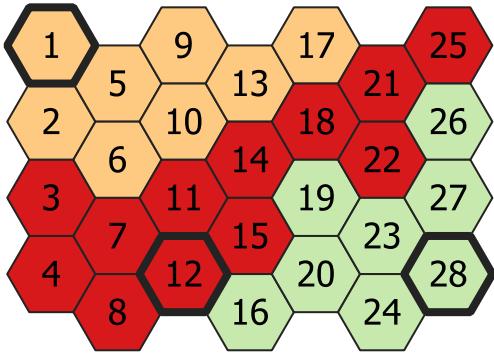

# Contiguity Introduction

**Question:** Why is contiguity important?

- Prevents **isolated areas**
- Ensures **contiguous patrol routes**
- Maintains **operational coherence**

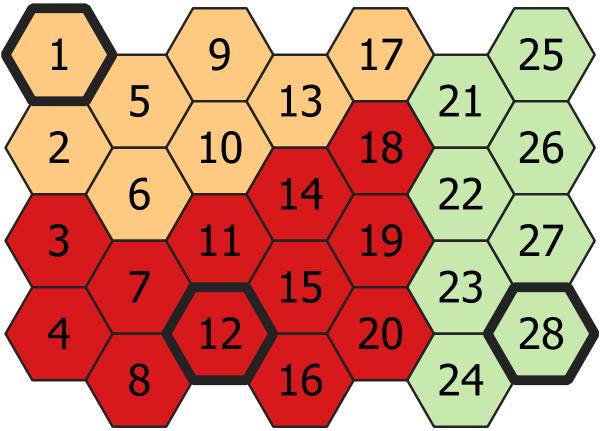

# What is compactness?

## Compactness

Compactness has **no univocal definition**; a district is commonly declared compact if it is ‘somehow round-shaped and undistorted’ (Kalcsics, Nickel, and Schröder 2005).

# Contiguity and Compactness

**Question:** Are our resulting districts based on the model contiguous and compact?

- This depends on  $t_{i,j}$
- If Euclidean distance
  - Districts will be contiguous
  - Likely of compact shape

# Compactness p-Median

**Question:** Is this likely for police service districting?

- No, as we minimize the driving time within a city
- Highways, Tunnels, etc.
- Multiplied by the differing number of requested cars
- This can contribute to distorted district shapes

# Contiguity Sets

## Additional Set and Parameter

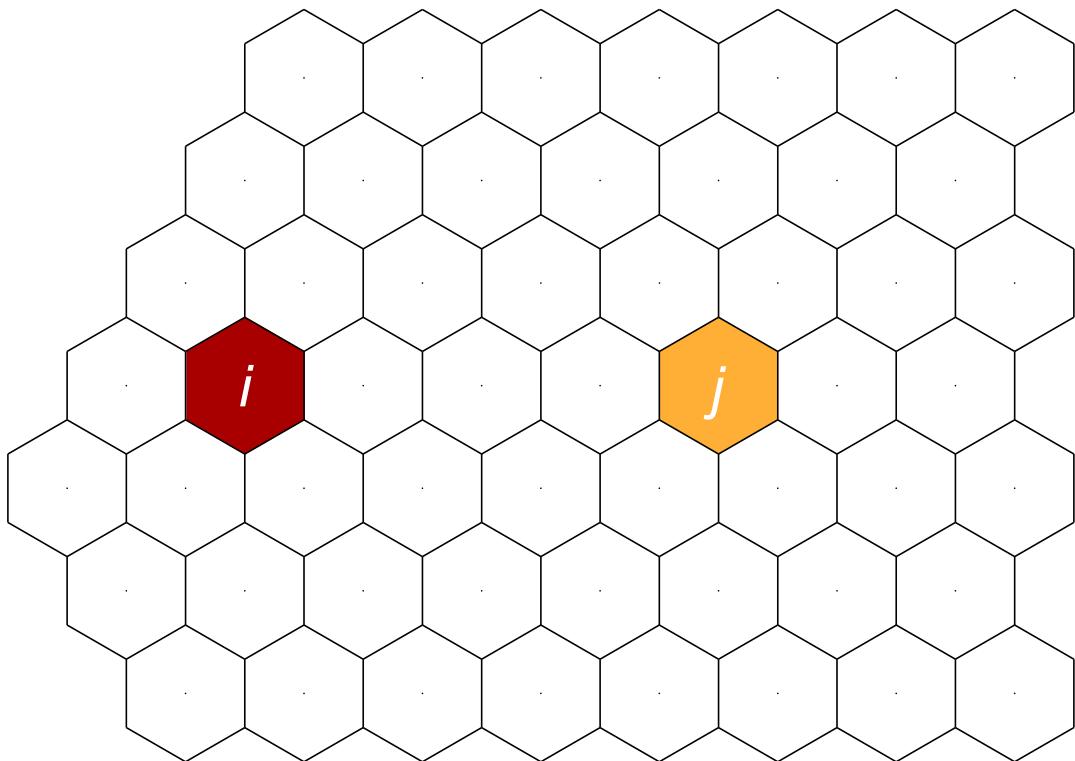

- $e_{i,j}$  - Euclidean distance between centroids
- $\mathcal{A}_j$  - Sets of BAs adjacent to BA  $j$

$$\mathcal{N}_{i,j} = \{v \in \mathcal{A}_j | e_{i,v} < e_{i,j}\} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J}$$

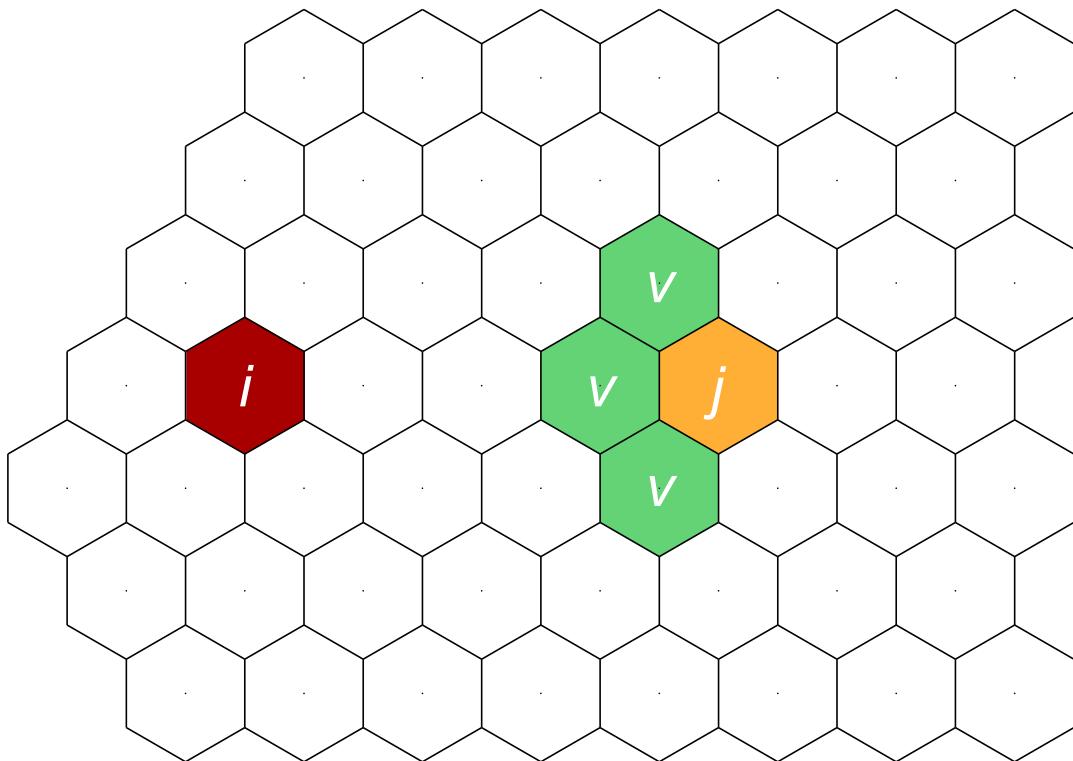

### The idea

BAs closer to department  $i$  than BA  $j$  on euclidian distance and adjacent to  $j$ !

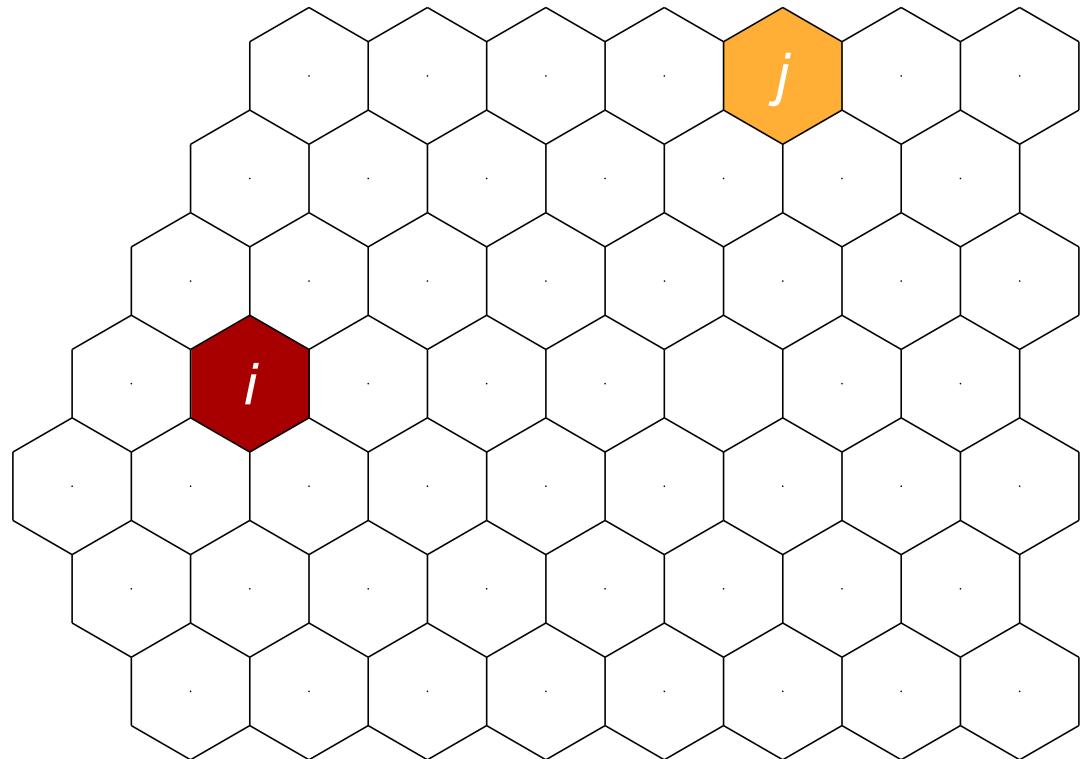

# Example A

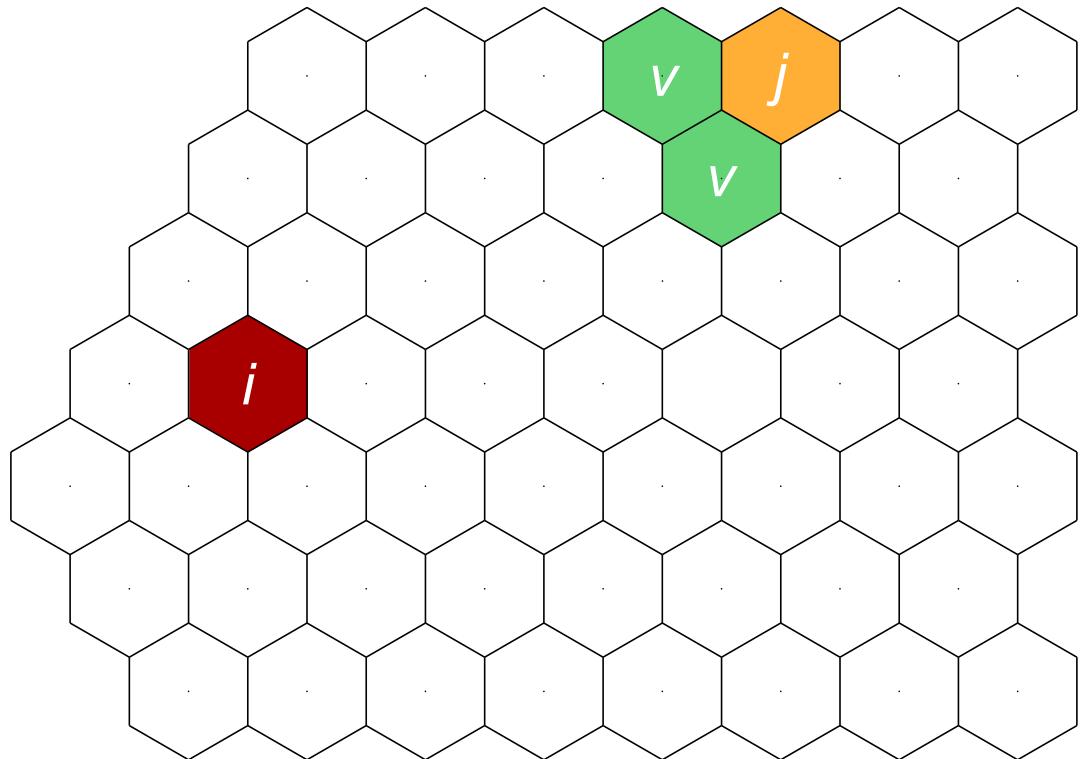

# Example A

# Example B

# Example B

# Enforcing Contiguity

All districts have to be contiguous

$$X_{i,j} \leq \sum_{v \in \mathcal{N}_{i,j}} X_{i,v} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J} \setminus \mathcal{A}_i : i \neq j$$

## ! The idea

At least **one department** has to be assigned to a BA that is adjacent to BA  $j$  and closer to department  $i$ !

# Contiguity and Compactness

All districts have to be contiguous and compact

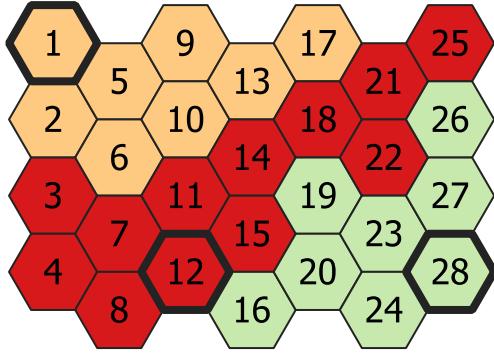

$$X_{i,j} \leq \sum_{v \in \mathcal{N}_{i,j}} X_{i,v} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J} \setminus \mathcal{A}_i : |\mathcal{N}_{i,j}| = 1 \wedge i \neq j$$

$$2X_{i,j} \leq \sum_{v \in \mathcal{N}_{i,j}} X_{i,v} \quad \forall i \in \mathcal{I}, \forall j \in \mathcal{J} \setminus \mathcal{A}_i : |\mathcal{N}_{i,j}| > 1 \wedge i \neq j$$

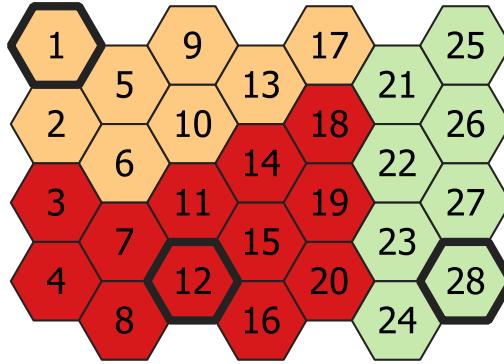

## ! The idea

At least **two departments** have to be assigned to a BA that is adjacent to BA  $j$  and closer to department  $i$ !

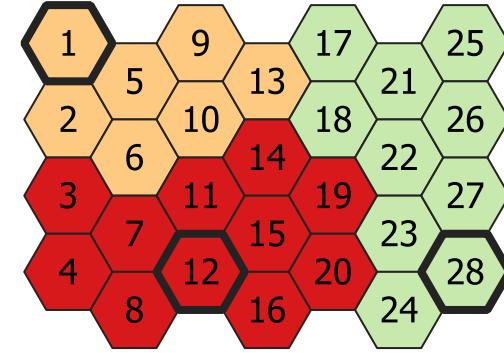

# Comparison

One department

Two departments

Up to three departments

Why does this work?

Due to the constraints, there is **always a path back** to the department if a BA is assigned to a department!

# Model Characteristics

# Characteristics

## Questions: On model characteristics

- Is the model formulation linear/ non-linear?
- What kind of variable domains do we have?
- What do you think, can the model be solved quickly?
- Have we prevented isolated districts?

# Model Assumptions

## Questions: On model assumptions

- What assumptions have we made?
- Use Euclidean distances to approximate driving time?
- Can we rely on incident data collected by the police?

# Implementation and Impact

# Overview of Studies

**Question:** Where did we apply our model?

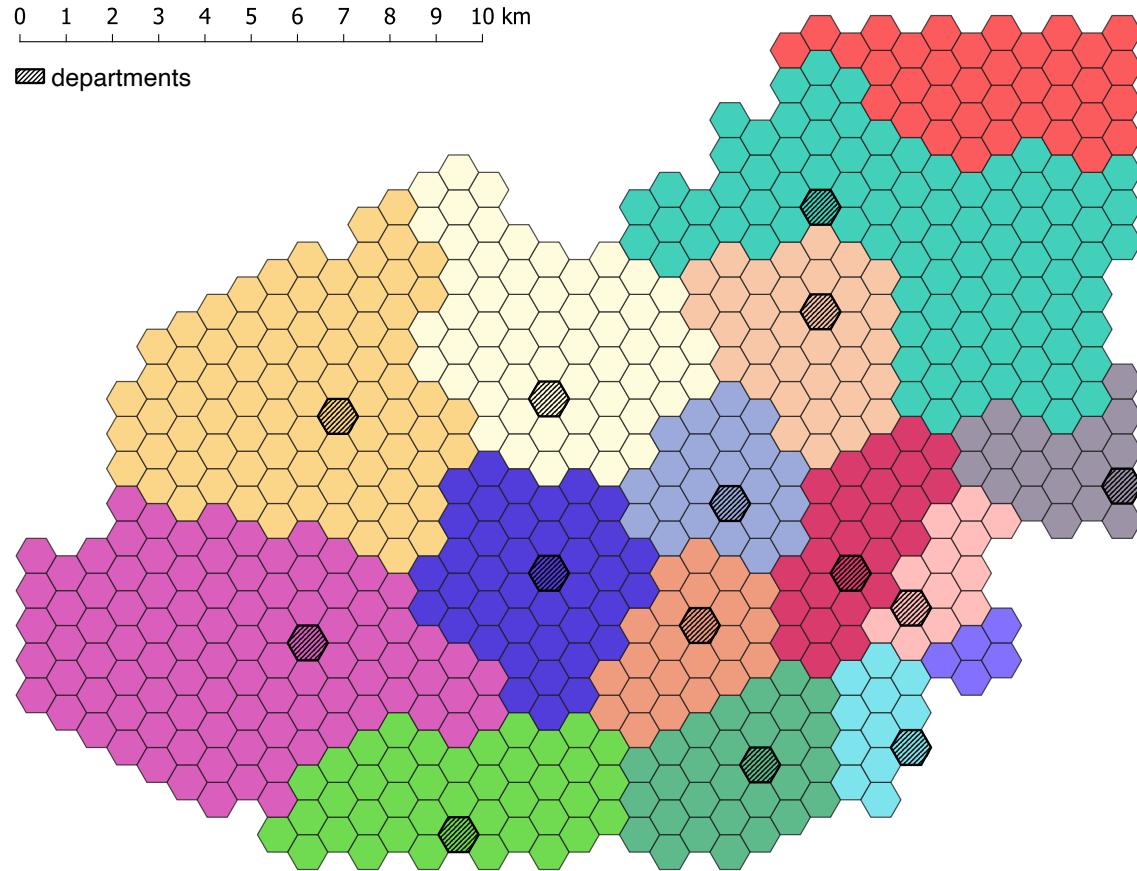

- Two distinct environments:
  1. Large metropolitan area (Germany)
  2. Rural region (Belgium)
- Different challenges and requirements
- Focus on **response time optimization**

# German Metropolitan Case

- 1.8 mio incidents (2015-2019)
- ~20 department locations
- 1,596 basic areas
- Dense urban environment

**Goal:** Redesign districts to improve response time.

# German Metropolitan Results

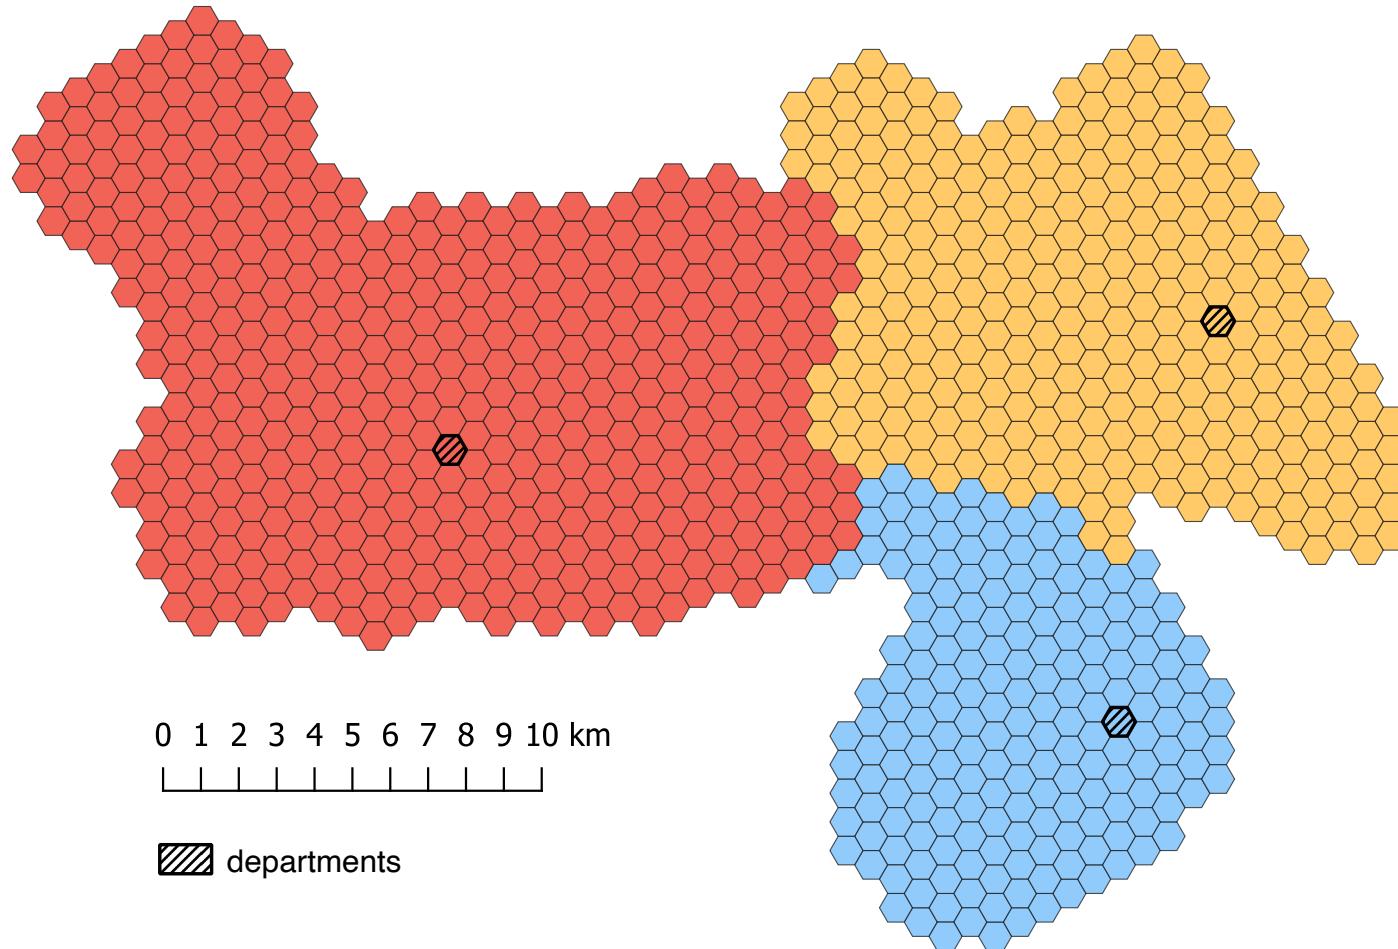

# Belgian Rural Case

- 50,000 incidents (2019-2020)
- 2 existing + 1 planned location
- 1,233 basic areas
- Dispersed rural setting

**Goal:** Optimize coverage with limited resources.

# Belgian Rural Results

# Simulation Framework

**Question:** How did we validate the results?

- Spatial and temporal patterns
- Shift schedules
- Priority handling
- Rush hours
- Inter-district support
- Variable driving times

# Results

- Response time **reduction up to 14.52%**
- Better **workload distribution**
- Improved **coverage equity**
- More efficient **resource utilization**

 **Important**

All improvements are **without additional staff!**

# Conclusions

1. Model adaptability crucial
2. Local context matters
3. Stakeholder buy-in essential
4. Data quality critical

Tip

Success requires balancing theoretical optimization with practical constraints!

# Future Applications

**Question:** Where else could this approach be useful?

- Other emergency services
- Different urban contexts
- Resource allocation problems
- Service territory design

Note

The methodology is adaptable to various public service optimization scenarios.

# Wrap Up

And that's it for todays lecture!

We now have covered districting problems and are ready to start solving some tasks in the upcoming tutorial.
