Lecture V - Planning in Breweries

Applied Optimization with Julia

Dr. Tobias Vlćek
University of Hamburg

Introduction

Case Study

- Large brewery
- Brews and sells beverages
- Production planning by hand
- Planner has a **lot of experience**
- But will retire soon

Challenges

- Strong competition
- Customer demand is changing
- Craft beer gains popularity
- Variety of drinks is increasing
- **Batch sizes are getting smaller**

Different costs

- Plant can fill **multiple types**
- Time depends on **type and batch**
- **Changing type** leads to setup costs for preparation and cleaning
- **Unsold beer bottles** can be **stored in a warehouse**
- This leads to **inventory costs**

Learning Objectives

After this lecture, you will be able to:

- **Formulate** the Capacitated Lot-Sizing Problem (CLSP)
- **Explain** the trade-off between setup and inventory holding costs
- **Recognize and construct** Big-M constraints
- **Discuss** the assumptions and limits of a finite planning horizon

One Bottling Line

Question: Many beers share it. Where is the challenge?

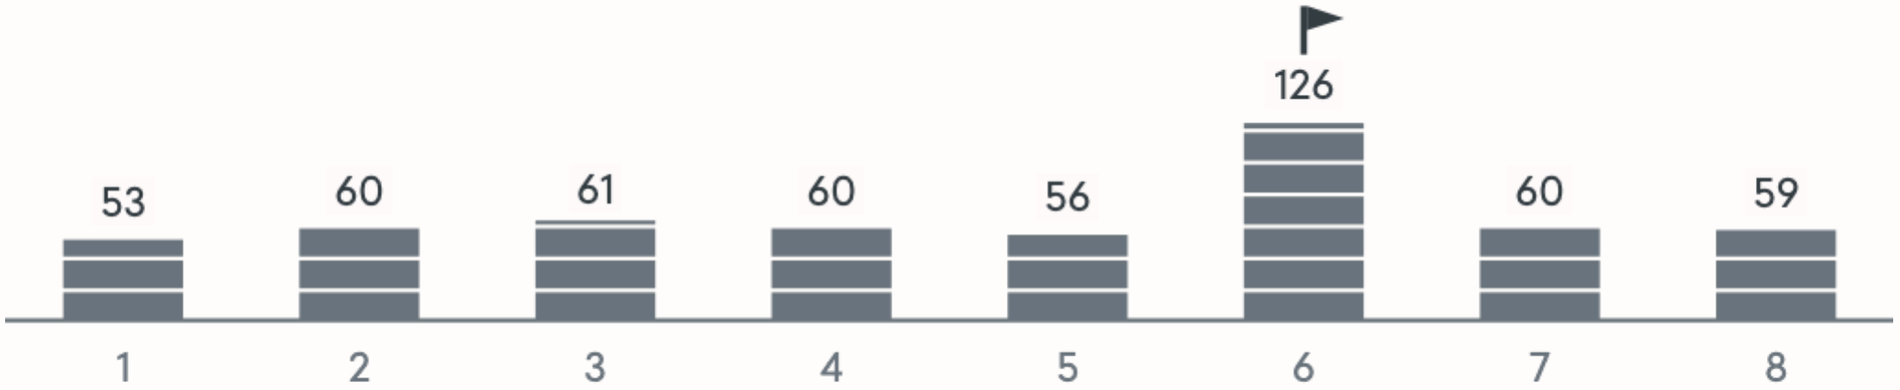

Photo: Waldemar Brandt, Unsplash

Your Turn

The planner retires, and you take over. Tap a week to switch its bottling run on or off: a run bottles every crate until the next run. Each run costs 400 € for the setup, each crate costs 2 € per week in the warehouse. A flag marks the harbour festival.

Orders in crates

Bottling runs, tap a week

1	2	3	4	5	6	7	8
53	60	61	60	56	126	60	59

In the warehouse

1	2	3	4	5	6	7	8
0	0	0	0	0	0	0	0

Runs: 8 × 400 €

Stock: 0 × 2 €

You 3,200 €

Ready: press Optimize to compare with the best plan.

Problem Structure

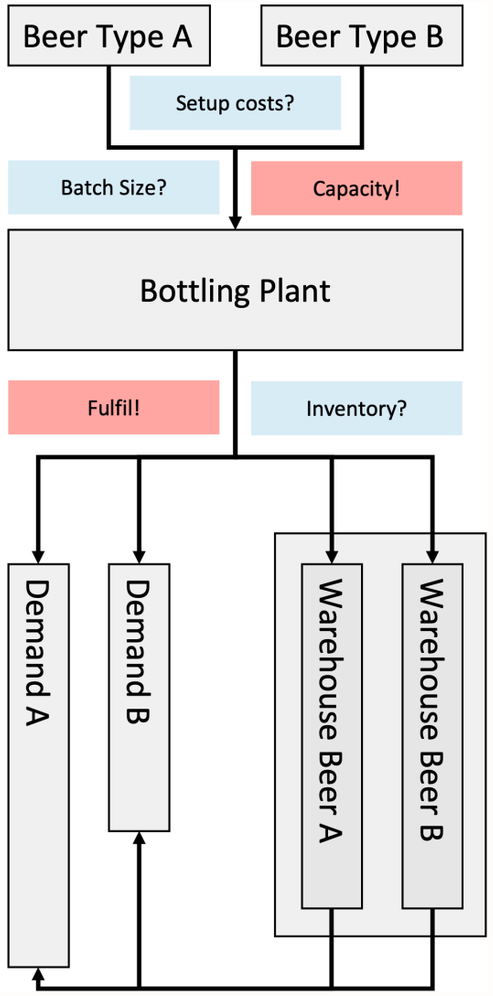

Objective

Question: What could be the objective?

Minimize the combined setup and inventory holding cost while satisfying the demand and adhering to the production capacity.

Trade-Off

Question: What is the trade-off?

Larger batches require **less setup cost per bottle**, but increase the storage cost.

Available Sets

Question: What are sets again?

Sets are **collections of objects**.

Question: What could be the sets here?

- $\mathcal{I}$ - Set of beer types indexed by $i \in \{1, 2, \ldots, |\mathcal{I}|\}$
- - Set of time periods indexed by

Available Parameters

Question: What are possible parameters?

- - Available time on the bottling plant in period
- - Time used for bottling one unit of beer type
- - Setup time for beer type
- - Setup cost of beer type
- - Inventory holding cost for one unit of beer type
- - Demand of beer type in period

Decision Variables?

ⓘ **We have the following sets:**

- Beer types indexed by
- Time periods of the planning horizon indexed by

ⓘ **Our objective is to:**

Minimize the combined setup and inventory holding cost while satisfying the demand and adhering to the production capacity.

Question: What could be our decision variable/s?

Decision Variables

- - Inventory of type at the end of
- - 1, if type is bottled in , 0 otherwise
- - Batch size of type in

Model Formulation

Objective Function?

Our objective is to:

Minimize the combined setup and inventory holding cost while satisfying the demand and adhering to the production capacity.

Question: What could be our objective function?

We need the following variables:

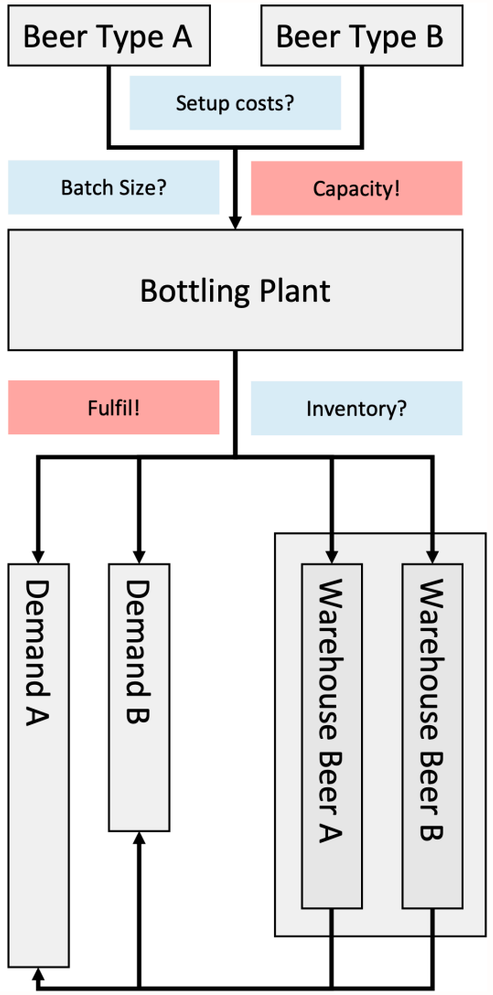

- - Inventory of type at the end of
- - 1, if type is bottled in , 0 otherwise

Objective Function

ⓘ We need the following parameters:

- - Setup cost of beer type
- - Inventory holding cost for one unit of beer type

Constraints

Question: What constraints?

- Transfer **unused** inventory
- **Fulfill** the customer demand
- **Set up** beer types
- Calculate **batch size** per set-up
- Compute **remaining** inventory
- **Limit** the bottling plant

Demand/Inventory Constraints?

The goal of these constraints is to:

Consider the current inventory and batch sizes and compute the remaining inventory.

We need the following variables and parameters:

- - Inventory of beer type at the end of period
- - Batch size of beer type in
- - Demand of beer type in period

Question: What could the constraint look like?

Demand/Inventory Constraints

with , as the warehouse starts empty.

ⓘ **Remember, these are the variables and parameters:**

- - Inventory of beer type at the end of period
- - Batch size of beer type in
- - Demand of beer type in period

Why Fix the Starting Inventory?

Question: Why do we have to fix ?

Otherwise, the solver could invent free starting inventory and would never need to bottle anything for the first weeks!

Setup Constraints?

The goal of these constraints is to:

Set up beer types in all periods where the batch size is 0.

We need the following variables and parameters:

- - 1, if beer type is bottled in period , 0 otherwise
- - Batch size of beer type in
- - Demand of beer type in period

Question: What could the second constraint be?

Setup Constraints

Question: Do you know this type of constraint?

This type of constraint is called a **“Big-M”** constraint!

- M (here) is a large number
- It is coupled with a binary variable (here)
- **Like an if-then constraint**

Capacity Constraints?

The goal of these constraints is to:

Limit the capacity of the bottling plant per period.

We need the following variables and parameters:

- - 1, if beer type is bottled in period , 0 otherwise
- - Batch size of beer type in
- - Available time on the bottling plant in period
- - Time used for bottling one unit of beer type
- - Setup time for beer type

Capacity Constraints

Question: What could the third constraint be?

It uses more parameters than the previous constraints, but it is easier to understand.

And that's basically it!

CLSP: Objective Function

The complete model is known as the **Capacitated Lot-Sizing Problem (CLSP)**.

> **The goal of the objective function is to:**
>
> Minimize the combined setup and inventory holding cost while satisfying the demand and adhering to the production capacity.

CLSP: Constraints

Our constraints ensure:

Demand is met, inventory transferred, setup taken care of, and capacity respected.

CLSP: Variable Domains

> **The variable domains make sure that:**
>
> The binary setup variable is either 0 or 1 and that the inventory and batch size are non-negative.

Question: Why is a continuous batch size acceptable here?

Rounding a batch of thousands barely changes the cost.

Julia Implementation

Variables in Julia

Question: How could we formulate the variables in Julia?

```julia
using JuMP, HiGHS
beer_types = ["IPA", "Lager", "Stout"] # Beer types
periods = 1:3 # Time periods (weeks)
clsp_model = Model(HiGHS.Optimizer)
set_silent(clsp_model) # Hide the solver output
```

```julia
@variable(clsp_model, Y[i in beer_types, t in periods], Bin)
@variable(clsp_model, X[i in beer_types, t in periods] >= 0)
@variable(clsp_model, W[i in beer_types, t in 0:last(periods)] >= 0)
```

```
2-dimensional DenseAxisArray{JuMP.VariableRef,2,...} with index sets:
    Dimension 1, ["IPA", "Lager", "Stout"]
    Dimension 2, 0:3
And data, a 3×4 Matrix{JuMP.VariableRef}:
 W[IPA,0]    W[IPA,1]    W[IPA,2]    W[IPA,3]
 W[Lager,0]  W[Lager,1]  W[Lager,2]  W[Lager,3]
 W[Stout,0]  W[Stout,1]  W[Stout,2]  W[Stout,3]
```

Note, how we declare the inventory also for period 0!

Objective Function in Julia

```julia
c = Dict("IPA" => 0.1, "Lager" => 0.1, "Stout" => 0.1) # Holding costs
f = Dict("IPA" => 5000, "Lager" => 4000, "Stout" => 6000) # Setup costs
```

```julia
@objective(clsp_model, Min,
    sum(c[i] * W[i,t] + f[i] * Y[i,t]
        for i in beer_types, t in periods)
)
```

Data for our Small Brewery

We need the demand , capacity , and times , :

```
d = Dict( # Demand per beer type and week
    "IPA"   => [300, 800, 500],
    "Lager" => [600, 500, 800],
    "Stout" => [200, 300, 250],
)
a = [1800, 1800, 1800] # Capacity per week in minutes
b = Dict("IPA" => 0.9, "Lager" => 0.6, "Stout" => 1.2) # Min. per bottle
g = Dict("IPA" => 60, "Lager" => 40, "Stout" => 80) # Setup in minutes
```

Constraints in Julia

The constraints map almost one-to-one from the math:

```
@constraint(clsp_model, [i in beer_types],
    W[i,0] == 0) # The warehouse starts empty
@constraint(clsp_model, [i in beer_types, t in periods],
    W[i,t-1] + X[i,t] - W[i,t] == d[i][t])
```

```
@constraint(clsp_model, [i in beer_types, t in periods],
    X[i,t] <= sum(d[i]) * Y[i,t]) # Big-M setup constraint
@constraint(clsp_model, [t in periods],
    sum(b[i] * X[i,t] + g[i] * Y[i,t] for i in beer_types) <= a[t])
```

Solving the Model

```
1 optimize!(clsp_model)
2 println("Status: ", termination_status(clsp_model))
3 println("Total cost: ", objective_value(clsp_model))
```

```
Status: OPTIMAL
Total cost: 28130.0
```

Of the 28,130 total cost, 28,000 are setup costs and only 130 are inventory holding costs — but what does the plan look like?

The Production Plan

```
for i in beer_types
    println(rpad(i, 8),
        "X = ", rpad(string([round(Int, value(X[i,t])) for t in periods]), 18),
        "W = ", [round(Int, value(W[i,t])) for t in periods])
end
```

```
IPA      X = [300, 1300, 0]    W = [0, 500, 0]
Lager    X = [600, 500, 800]   W = [0, 0, 0]
Stout    X = [750, 0, 0]       W = [550, 250, 0]
```

- Stout is bottled **only once**: week 1 covers all three weeks, saving two setups at 6,000 each
- Lager is bottled every week, as the plant capacity is too tight to batch it
- IPA batches the demand of week 3 into week 2

Model Characteristics

Recap on some Basics

There exist several types of optimization problems:

- **Linear (LP):** Linear constraints and objective function
- **Mixed-integer (MIP):** Linear constraints and objective function, but discrete variable domains
- **Quadratic (QP):** Quadratic constraints and/or objective
- **Non-linear (NLP):** Non-linear constraints and/or objective
- **And more!**

Recap on Solution Algorithms

- **Simplex algorithm** to solve LPs
- **Branch & Bound** to solve MIPs
- **Outer-Approximation** for mixed-integer NLPs
- **Matheuristics** (e.g., Fix-and-Optimize, …)
- **Metaheuristics** (e.g., tabu search, genetic algorithms, …)
- **Decomposition** methods (Lagrange, Benders, …)
- **Heuristics** (greedy, construction method, n-opt, …)
- **Graph theoretical methods** (network flow, shortest path)

Model Characteristics

Questions: On model characteristics

- Is the model formulation linear/ non-linear?
- What kind of variable domains do we have?
- What kind of solver could we use?
- Can the Big-M constraint be tightened?

Tightening the Big-M

Question: How small can we make M without cutting off solutions?

- Production in period only serves demand from onward:
- Capacity limits a batch as well:

The **smaller** of the two is the tighter bound — and tighter formulations are usually solved faster!

Model Assumptions

Questions: On model assumptions

- What assumptions have we made?
- What is the problem with the planning horizon?
- Any idea how to solve it?

> **End-of-horizon effect**
>
> The model plans no inventory for demand after week , as it does not know about it. In practice, this is solved by re-planning on a **rolling horizon**.

Impact

Can this be applied?

Scale as a Problem

Solving the problem with commercial solvers is not tractable, as it takes too long.

Scale of the Case Study

- 220 finished products
- 100 semi-finished products
- 13 production resources
- 8 storage resources
- 3 main production levels
- 52 weeks planning horizon

Our CLSP is the **single-level core**: the real case is multi-level, with semi-finished products and storage.

Any idea what could be done?

Heuristics and Optimization

- Multi-level Capacitated Lot-Sizing Problem
- Heuristic fix and optimize approach [1]
- Operating cost reduction by 5% and planning effort by 40%

> **And that's it for today's lecture!**
>
> We now have covered the basics of the CLSP and are ready to start solving some tasks in the upcoming tutorial.

Questions?
